example.s

# AT&T Assembly Syntax(1)

- Format

**operation source,destination**

- Example: move the hexadecimal value 2 into the register al.

**movb \$0x02,%al**

# AT&T Assembly Syntax(2)

- AT&T immediate operands are preceded by \$
- AT&T register operands are preceded by %
- AT&T absolute (as opposed to PC relative) jump/call operands are prefixed by \*
- AT&T and Intel syntax use the opposite order for source and destination operands. Intel 'add eax, 4' is 'addl \$4, %eax'. The 'source, dest' convention is maintained for compatibility with previous Unix assemblers.
- In AT&T syntax the size of memory operands is determined from the last character of the opcode name. Opcode suffixes of 'b', 'w', and 'l' specify byte (8-bit), word (16-bit), and long (32-bit) memory references.
- The AT&T assembler does not provide support for multiple segment programs. Unix style systems expect all programs to be single segment

# Register Naming

- **32-bit registers:** ``%eax'` (the accumulator), ``%ebx'`, ``%ecx'`, ``%edx'`, ``%edi'`, ``%esi'`, ``%ebp'` (the frame pointer), and ``%esp'` (the stack pointer).
- **16-bit low-ends of these:** ``%ax'`, ``%bx'`, ``%cx'`, ``%dx'`, ``%di'`, ``%si'`, ``%bp'`, and ``%sp'`.
- **8-bit registers:** ``%ah'`, ``%al'`, ``%bh'`, ``%bl'`, ``%ch'`, ``%cl'`, ``%dh'`, and ``%dl'` (These are the high-bytes and low-bytes of ``%ax'`, ``%bx'`, ``%cx'`, and ``%dx'`)

# Memory References

An Intel syntax indirect memory reference of the form

$$[\text{base} + \text{index} * \text{scale} + \text{disp}]$$

is translated into the AT&T syntax

$$\text{disp}(\text{base}, \text{index}, \text{scale})$$

# Entering a Function

- When entering a function, the following operations are invoked

```
pushl %ebp
```

```
movl %esp,%ebp
```

**Note that esp is pushed PC value  
(4 bytes)**

# Returning from a Function

- When returning from a function, leave operation invoked

**leave**

is equivalent to

```
movl    %ebp, %esp  
popl    %ebp
```

# Showing Contents of Registers in the gdb debugger
